evolMC demo

Grady Weyenberg

November 22, 2013

evolMC is a framework for doing Monte-Carlo simulations.

0.1 Univariate and multivariate sampling

We wish to use a metropolis sampler to draw from a distribution with density

$$f(x) \propto \frac{\sin(x)}{x} \cdot 1_{(0,\pi)}(x).$$

We can use a uniform distribution on (-1,1) to propose distances to jump from the current location. Since the proposal distribution is symmetric, this is enough information to implement a Metropolis updater.

```
fn <- function(x) log(sin(x)/x * (0 < x) * (x < pi))
propose <- function(x) x + runif(length(x), -1, 1)
updater <- metropolis(fn, propose)</pre>
```

A Markov chain is formed by iteratively calling the updating function starting with some initial value.

```
chain <- iterate(n = 10000, fn = updater, init = 1)
summary(chain)

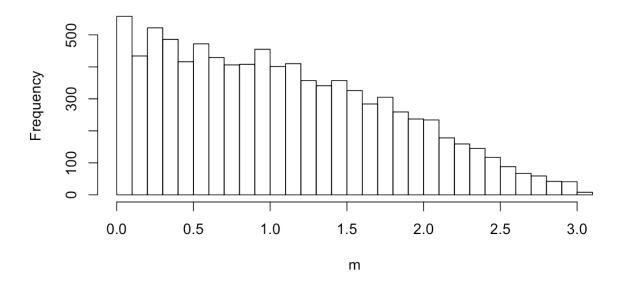

## Discarding first 1000 states.
## mean se 2.5% 97.5%

## 1.07100 0.72155 0.03758 2.58650

hist(chain, breaks = "fd")

## Discarding first 1000 states.</pre>
```

Histogram of m

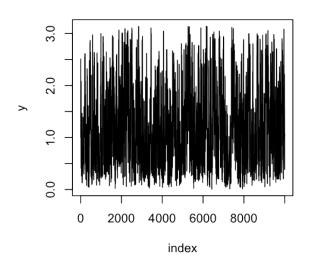

Of course, multivariate distributions may also be sampled.

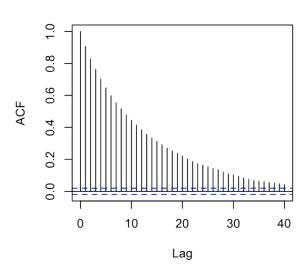

x 0.0 2.00 4000 6000 8000 index

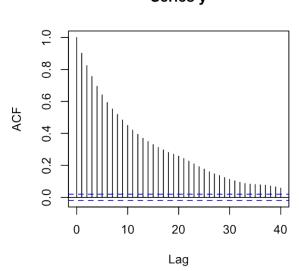

Traceplot of 1 populations

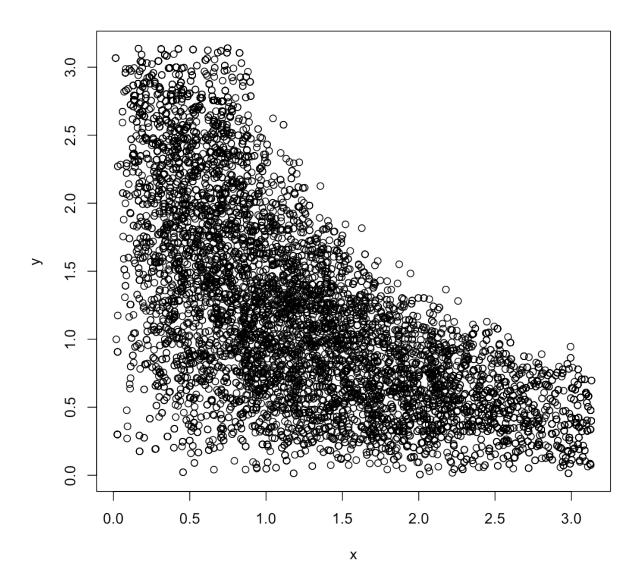

Series x

Series y

plot(t(simplify2array(chain2)[1, ,]))

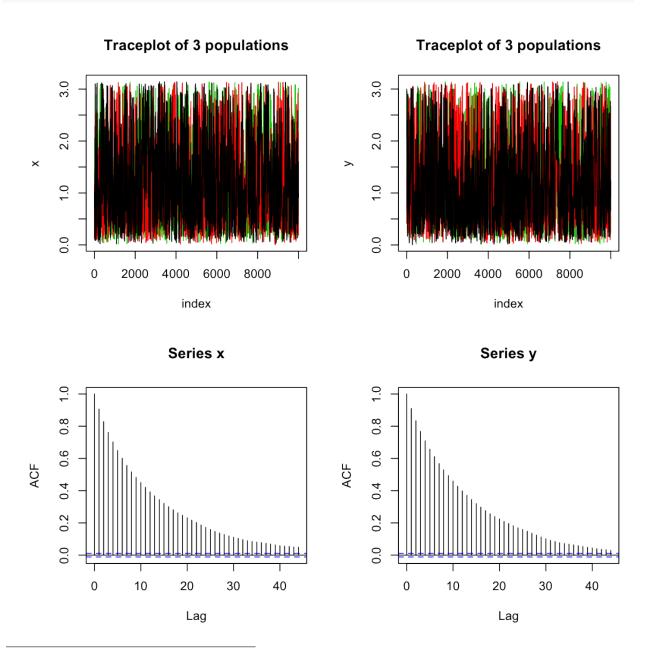

0.2 Multiple chains in parallel

If the target density returns a vector instead of a scalar, we can run multiple chains in parallel. (In this case the state object is a matrix with individuals in rows.) In this situation, the proposal updater should update the entire population.

```
chain3 <- iterate(100, updater, init = rbind(0.1, 0.5, 2.5, 3.1))
## Error: invalid arguments
plot(chain3)
## Error: object 'chain3' not found</pre>
```

Multiple chains of multivariate samples are also possible, as long as a logical vector of the same length as that returned by the density function will "correctly" subset individuals from the population state object. ¹

```
mvt2 <- function(x) apply(x, 1, mvtarget)
mvup2 <- metropolis(mvt2, propose)
init <- rbind(c(x = 1, y = 3), c(0.1, 0.5), c(1, 1))
chain4 <- iterate(10000, mvup2, init)
plot(chain4)</pre>
```

¹Thus, a population can be a vector, a matrix with individuals in rows, or a list. Some convenience methods such as print, summary, plot, hist, etc., assume a population is a matrix, but this is not strictly required.

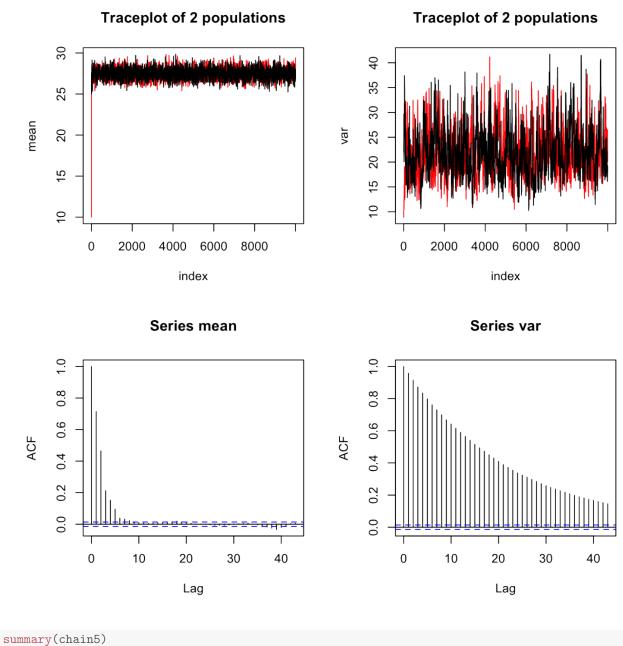

0.3 Gibbs sampling

A gibbs updater calls several updating functions sequentially. Here we find Baysean location-scale parameter estimates for a t-distribution likelihood with known degrees of freedom 5/2. The model specification in this case is $y|\mu, w \sim N(\mu, w^{-1})$ and $w|\sigma^2, \nu \sim G(\nu/2, \sigma^2\nu/2)$, with priors $\mu \sim N$ and $\sigma^2 \sim G$.

```
newcomb \leftarrow c(28, -44, 29, 30, 26, 27, 22, 23, 33, 16, 24, 29, 24, 40, 21, 31,
    34, -2, 25, 19, 24, 28, 37, 32, 20, 25, 25, 36, 36, 21, 28, 26, 32, 28,
    26, 30, 36, 29, 30, 22, 36, 27, 26, 28, 29, 23, 31, 32, 24, 27, 27, 27,
    32, 25, 28, 27, 26, 24, 32, 29, 28, 33, 39, 25, 16, 23)
##' Full conditional updater for mu
f.m <- function(state, ...) {</pre>
    k <- seq_len(ncol(state) - length(newcomb))</pre>
    w <- rowSums(state[, -k])</pre>
    mu <- (state[, -k] %*% newcomb)/(1e-04 + w)
    sd <- 1/sqrt(1e-04 + w)
    n <- nrow(state)</pre>
    state[, 1] <- rnorm(n, mu, sd)
    state
##' Full conditional updater for sigma^2
f.v <- function(state, df = FALSE) {</pre>
    nu <- if (df)
        1/state[, 3] else 5
    k <- seq_len(ncol(state) - length(newcomb))</pre>
    n <- ncol(state[, -k])</pre>
    rates <- 0.1 + rowSums(state[, -k]) * nu/2
    state[, 2] \leftarrow rgamma(nrow(state), 0.1 + n * nu/2, rates)
    state
##' Full conditional updater for w
f.w <- function(state, df = FALSE) {</pre>
    nu <- if (df)
        1/state[, 3] else 5
    k <- seq_len(ncol(state) - length(newcomb))</pre>
    rate <- (nu * state[, 2] + t(apply(state, 1, function(row) (newcomb - row[1])^2)))/2
    state[, -k] <- rgamma(length(state[, -k]), (nu + 1)/2, rate)
    state
```

The gibbs function is used to create a function which acts as the Gibbs updater.

```
init <- rbind(c(mean = 25, var = 22, rgamma(length(newcomb), 5/2, 22 * 5/2)),
     c(10, 10, rgamma(length(newcomb), 5/2, 10 * 5/2)))
newcomb.gibbs <- gibbs(f.m, f.v, f.w)
chain5 <- iterate(10000, newcomb.gibbs, init)
chain5 <- prune(chain5, TRUE, 1:2)
plot(chain5)</pre>
```

```
## Discarding first 1000 states.

## mean var

## mean 27.4908 21.995

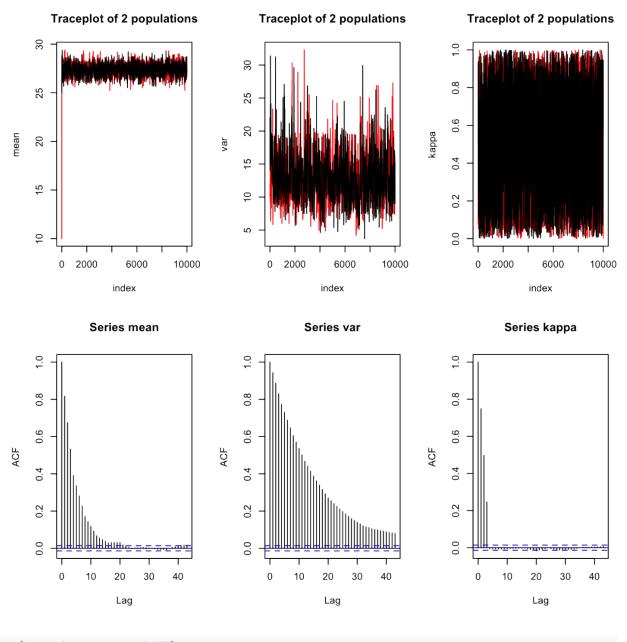

## se 0.6638 4.782

## 2.5% 26.1954 14.250

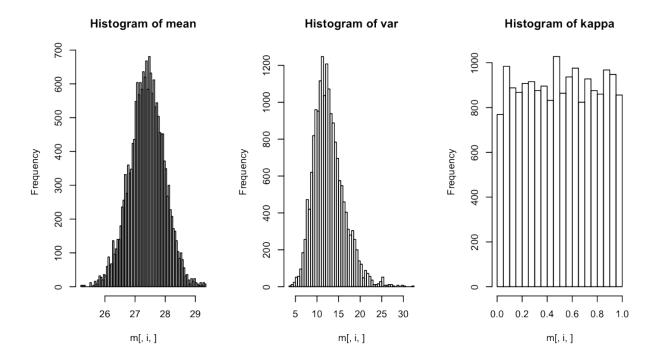

## 97.5% 28.8291 33.006
```

Of course, you can use a metropolis updater in place of a full conditional. Here we put a prior on $\nu^{-1} \sim E(1)T(0,1)$

```
dtexp <- function(x, rate = 1, min = 0, max = Inf, log = FALSE) {</pre>
    d \leftarrow dexp(x, rate) * (x >= min) * (x <= max)
    c <- pexp(max, rate) - pexp(min, rate)</pre>
    if (log)
        log(d/c) else d/c
posterior <- function(state) {</pre>
    if (!is.matrix(state))
        state <- matrix(state, 1)</pre>
    f \leftarrow function(x) sum(dt((newcomb - x[1])/sqrt(x[2]), 1/x[3], log = TRUE) -
    exp(apply(state, 1, f) + dnorm(state[, 1], sd = 100, log = TRUE) + dgamma(state[,
        2], 0.1, 0.1, log = TRUE) + dtexp(state[, 3], max = 1, log = TRUE))
kappa.prop <- function(state) {</pre>
   state[, 3] <- runif(nrow(state))</pre>
    state
init <- rbind(c(mean = 25, var = 22, kappa = 0.5, rgamma(length(newcomb), 5/2,
    22 * 5/2)), c(10, 10, 0.4, rgamma(length(newcomb), 5/2, 10 * 5/2)))
newcomb.chain3 <- gibbs(f.m, f.v, f.w, metropolis(posterior, kappa.prop))</pre>
chain4 <- iterate(10000, newcomb.chain3, init, df = TRUE)</pre>
chain4 <- prune(chain4, TRUE, 1:3)</pre>
summary(chain4)
## Discarding first 1000 states.
      mean var kappa
## mean 27.3842 12.734 0.5026
         0.5751 3.550 0.2870
## se
## 2.5% 26.2059 7.048 0.0316
## 97.5% 28.5032 20.956 0.9743
plot(chain4)
```

hist(chain4, breaks = "fd")
Discarding first 1000 states.

0.4 Parallel tempering

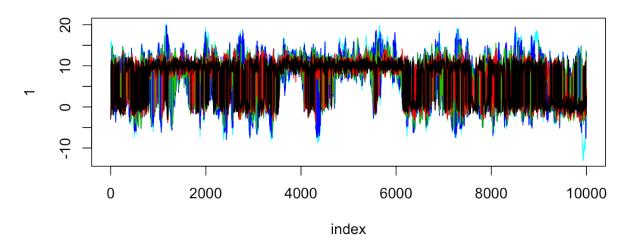

We want to sample from a distribution with separated modes. First we set up the target distribution function. This function should take a single individual and return the density of that individual.

```
f <- function(state) log(dnorm(state) + dnorm(state, 10))
```

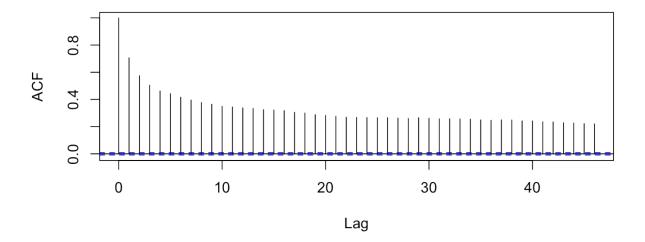

Now we can set up the parallel tempering updater. Function temper is similar to metropolis, but you must also provide a list of temperatures. (It is assumed that the number of individuals in the population will be the same as the number of temperature levels.)

```
temps <- c(1, 2, 4, 8, 15)
updater <- mutate(heat(f, temps), propose)
init <- rbind(-3, 0, 5, 10, 15)
gch <- iterate(10000, updater, init)
plot(gch)</pre>
```

Traceplot of 5 populations

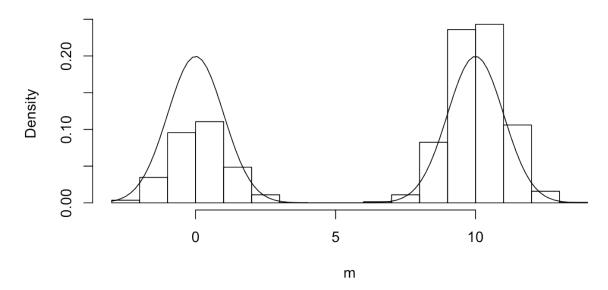

Series

```
xx <- prune(gch, 1, 1) #extract chain with correct distribution
```

```
hist(xx, freq = FALSE, breaks = "fd")
## Discarding first 1000 states.
curve((dnorm(x) + dnorm(x, 10))/2, add = TRUE)
```

Histogram of m

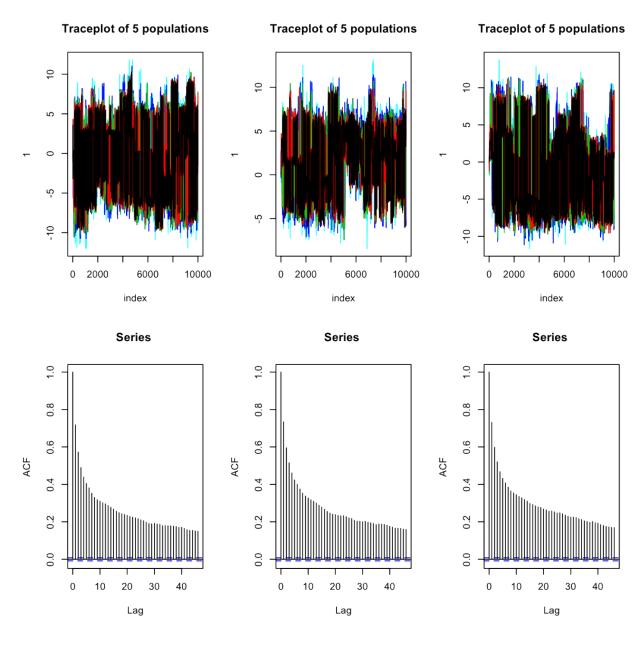

0.5 Evolutionary MC

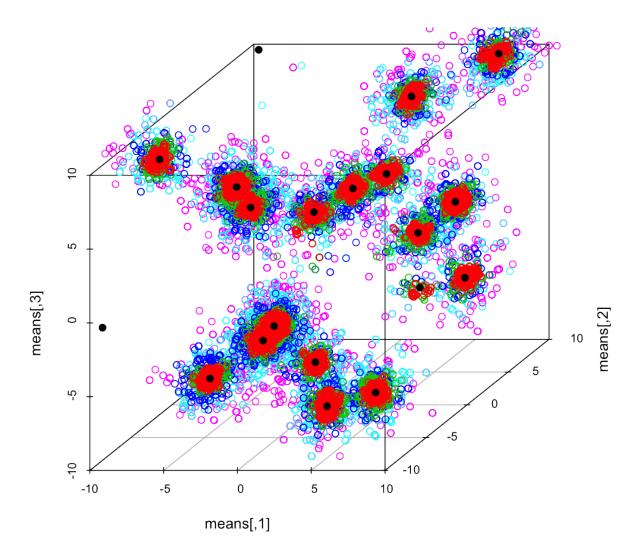

Here we go with the real-deal. Twenty part trivariate-gaussian mixure. The target function is a part of the evolMC package.

```
means <- t(replicate(20, runif(3, -10, 10)))
dmix <- function(x) log(target(x, means))
ladder <- heat(dmix, temps)
e <- seq(0.2, 3, length = 5)
runif3 <- function(x) x + runif(length(x), -e, e)
evolve <- gibbs(reproduce(ladder), mutate(ladder, runif3), p = c(1, 1))
init <- matrix(0, 5, 3)
# invisible(runif(100))
lineage <- iterate(10000, evolve, init)</pre>
```

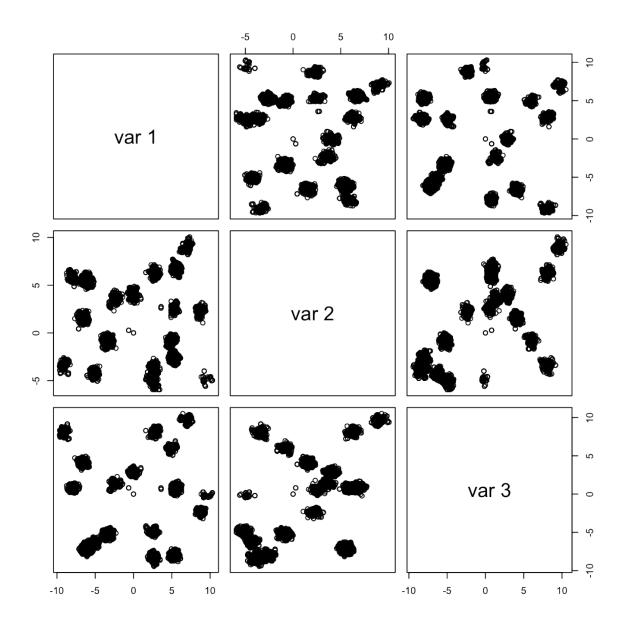

```
plot(lineage)
```

```
m <- aperm(simplify2array(lineage))
library(scatterplot3d)
pp <- scatterplot3d(means)
invisible(sapply(5:1, function(i) pp$points3d(m[, , i], col = i + 1)))
pp$points3d(means, col = 1, pch = 19)</pre>
```

pairs(m[, , 1])

library(rgl) plot3d(m[,,1]) plot3d(means,pch=19,size=15) ## sapply(1:5,function(i) points3d(m[,,i],col=i+1))
